# Negative sampling for Word2Vec

Parameterization of the skipgram model

$$p(c|w; \theta) = \frac{e^{v_c \cdot v_w}}{\sum_{c' \in C} e^{v_{c'} \cdot v_w}}$$

We want to maximize this log-likelihood

EXPENSIVE  
COMPUTATION!!!!

$$\arg \max_{\theta} \sum_{(w,c) \in D} \log p(c|w) = \sum_{(w,c) \in D} (\log e^{v_c \cdot v_w} - \log \sum_{c'} e^{v_{c'} \cdot v_w})$$

# Negative sampling for Word2Vec

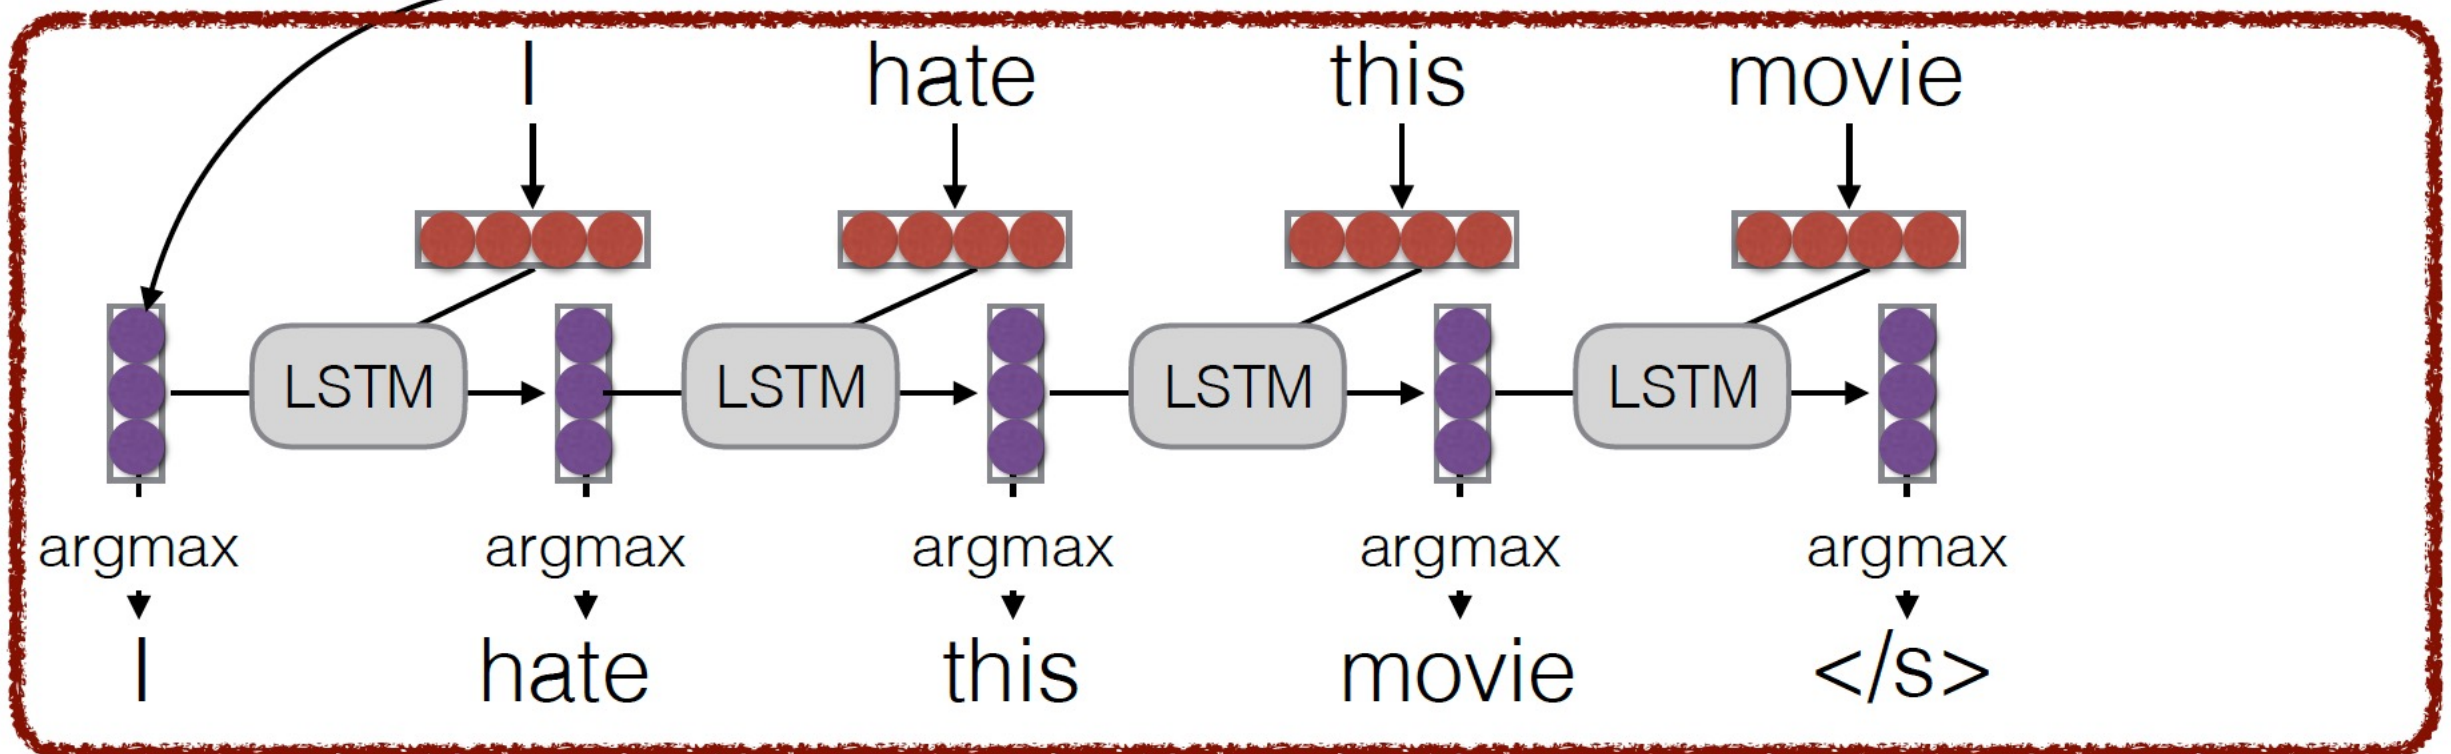

Instead of considering all the words in the vocabulary, consider a few “negative samples” for each “positive sample”. Typically, we consider 5 negative samples. Randomly sample 5 negative (false) contexts for each positive (correct) (word, context) in the dataset. In the equation below,  $D'$  is the set of word and context which are invalid i.e.,  $(w,c) \in D'$  means  $w$  never appears in the context  $c$  indicates the  $(w,c) \in D'$  is the set of all negative examples. The size of this set is much smaller than the original vocabulary size.

$$\arg \max_{\theta} \sum_{(w,c) \in D} \log \sigma(v_c \cdot v_w) + \sum_{(w,c) \in D'} \log \sigma(-v_c \cdot v_w)$$

Encoder

Decoder

# Sentence Representations

## Problem!

“You can’t cram the meaning of a whole %&!\$ing sentence into a single \$&!\*ing vector!”  
— Ray Mooney

- But what if we could use multiple vectors, based on the length of the sentence.

this is an example

this is an example

# Attention

# Why attention?

- Look into distant features
- Combine all the features in the sequence to produce a better feature representation

# Basic Idea

(Bahdanau et al. 2015)

- Encode each word in the sentence into a vector
- When decoding, perform a linear combination of these vectors, weighted by “attention weights”
- Use this combination in picking the next word

# Calculating Attention (1)

- Use “query” vector (decoder state) and “key” vectors (all encoder states)
- For each query-key pair, calculate weight
- Normalize to add to one using softmax

# Calculating Attention (2)

- Combine together value vectors (usually encoder states, like key vectors) by taking the weighted sum

- Use this in any part of the model you like

# A Graphical Example

# Attention Score Functions (1)

- $\mathbf{q}$  is the query and  $\mathbf{k}$  is the key
- **Multi-layer Perceptron** (Bahdanau et al. 2015)

$$a(\mathbf{q}, \mathbf{k}) = \mathbf{w}_2^\top \tanh(W_1[\mathbf{q}; \mathbf{k}])$$

- Flexible, often very good with large data
- **Bilinear** (Luong et al. 2015)

$$a(\mathbf{q}, \mathbf{k}) = \mathbf{q}^\top W \mathbf{k}$$

# Attention Score Functions (2)

- **Dot Product** (Luong et al. 2015)
  - No parameters! But requires sizes to be the same.

$$a(\mathbf{q}, \mathbf{k}) = \mathbf{q}^\top \mathbf{k}$$

- **Scaled Dot Product** (Vaswani et al. 2017)
  - Problem: scale of dot product increases as dimensions get larger

$$a(\mathbf{q}, \mathbf{k}) = \frac{\mathbf{q}^\top \mathbf{k}}{\sqrt{|\mathbf{k}|}}$$

- Fix: scale by size of the vector

# Convolutional neural network for text classification

- The task: Given a textual training data, train a CNN for classification/regression.
- Do you find any similarity with the CNN applied on images?

# Convolutional neural network for text classification

- Convert text to sequences

**vocabulary** - all unique words in a source of text

**token** - an integer value assigned to each word in the vocabulary

**token dictionary**

{**'the'**: 0, 'of': 1, 'so': 2, 'then': 3, 'you': 4, ... 'learn': 3191, ... 'artificial': 30297... }

**sample text**

**tokenized text**

*"the pettiness of the whole situation"* → [0, 121241, 1, 0, 988, 25910]
